Lateral bending will, you guessed it, cause compression on the side you are bending towards and tension on the other side. Torsional loading, which we usually just call torsion, is when forces acting on a structure cause a twist about its longitudinal axis.

Tension, Compression, Torsion, And Shear by Monique van Dijken

The five types of loads that can act on a structure are tension, compression, shear, bending and torsion. Tension: Two pulling (opposing) forces that stretch an object trying to pull it apart (for example, pulling on a rope, a car towing another car with a chain - the rope and the chain are in tension or are "being subjected to a tensile load").

Due to the differing structural loads anticipated at the wings; namely tension and compression. Bending stresses are expected at wing roots and especially in the case of large airliners, experienced at tips due to flexing of the wings again due to high loads emanating from the roots.

Internal Forces-Tension, Shear Force, Bending Moment

The compression force results in compressive stresses and tensile force in tensile stresses. Therefore, bending stress is a combination of compressive and tensile stresses due to internal moments. Since the stress across a beam section varies from compression to tension, there is a location at which stress is equal to zero.

...

Shafts are subjected to bending moments and torsional moments, which produce tensile and compressive stresses, and shear stresses respectively. Figure 10 shows a shaft with belt drives. The belt tensions cause bending in the shaft. To design a shaft you have to deal with the combined bending and torsional stress.

Intro to FEA

Both bending and compressive stresses are normal stresses. Bending stress is the stress generated due to transverse moment on a beam. This is the combination of tension and compression. If a beam is applied with bending moment as shown in picture, then the top fibers above Neutral Axis will experience Compressive stress and bottom fibers will experience Tensile stress.

Beam Bending Stresses and Shear Stress Pure Bending in Beams With bending moments along the axis of the member only, a beam is said to be in pure bending. Normal stresses due to bending can be found for homogeneous materials having a plane of symmetry in the y axis that follow Hooke's law. Maximum Moment and Stress Distribution

Forces can be internal or external • 5 types of recognized forces: compression, tension, torsion, shear & bending • 1. Compression - shortens or crushes • 2. Tension - stretches or pulls apart • 3. Torsion - twists • 4. Shear - pushes parts in opposite directions • 5. Bending - stretches and squashes at the same time. 11.

Shear Stress Normal stress is a result of load applied perpendicular to a member. Shear stress however results when a load is applied parallel to an area. Looking again at figure one, it can be seen that both bending and shear stresses will develop. Like in bending stress, shear stress will vary across the cross sectional area. Calculating the ...

There are five fundamental loading conditions; tension, compression, bending, shear, and torsion. Tension is the type of loading in which the two sections of material on either side of a plane tend to be pulled apart or elongated. Compression is the reverse of tensile loading and involves pressing the material together.
